The Impact of Fathers on Children

Peter B. Gray, PhD, Kermyt G. Anderson, PhD

October 2015

Introduction

Fathers are acknowledged as important influences on children in every society. What fathers do varies with respect to social context, which in turn shapes the variable impacts that fathers have on their children. Much of contemporary social science and policy research is concerned with fathers’ impacts on children’s socioemotional development. Yet material contributions made by fathers (“breadwinning”) remain central to an array of impacts on children, including with respect to children’s educational attainment and prospects for social success. Our aim in this entry is to briefly touch on the various impacts fathers have on their children.

Subject

Involved fathering is a defining characteristic of our species, with different features having evolved at different times and in different contexts. Yet paternal behaviours and roles also vary across and within sociocultural contexts, in turn yielding an array of influences on children. Fathers may provide protection, material resources (e.g., salary, livestock, inheritance), direct care (e.g., changing diapers, physical play), indirect care (such as arranging marriages in some cultures) and may serve as social models. Impacts on children may be measured in terms of
fertility (number of children), survival and health, educational attainment, socioemotional development (e.g., emotional capacity, language development) and reproductive parameters (e.g., children’s partnerships and fertility), among other outcomes.

Problems

While some scholars have decried how important two-parent families are to children’s emotional and behavioural regulation, others have suggested fathers’ services are quite substitutable and without much measurable impact. Such polarized views illustrate the challenges of specifying the key impacts of fathers on children, when and why they emerge, and how discussions can unfold without overly simplifying the complicated realities witnessed firsthand by service providers and scholars of interdisciplinary backgrounds and interests.

Moreover, a key problem in understanding the impacts of fathers on children is methodological: most studies are correlational and of unclear generalizability. A few longitudinal prospective studies provide rigorous insight but often at the expense of simplification of concepts (variables) in a limited number of countries. Experimental interventions (e.g., of assessing impacts of an obesity intervention on fathers) are rare, limiting the degree to which causal inference can be clearly drawn. Meta-analyses help in establishing robust patterns, but studies often use very different measures of both paternal involvement and children’s outcomes, making comparisons difficult.

Research Context

Different disciplines and areas of practice have often had distinct interests in fathers and children. Applied social services may be concerned with the impacts of father absence on children’s social development (including juvenile delinquency and engagement in criminal activities), on the reasons why men do or do not provide child support, or the role of father figures in child physical abuse. Other policy-oriented scholars may be interested in socially engineering more invested fathers with an eye toward enhancing child outcomes, such as increased high school graduation rates. Sociologists may be primarily concerned with socioeconomic and ethnic differences in father-child dynamics within Western countries. Evolutionary-minded scholars seek to understand the historical and adaptive bases of paternal behaviour and child development, including with respect to other animals. Anthropologists may pay more attention to the role of fathers in non-Western societies.
**Key Research Questions**

What are the impacts of fathers on children?

How do those impacts vary by social context?

How do changing family dynamics shape fathers’ roles and influences on children’s development?

What are the mechanisms by which fathers impact children?

Has the increase of unmarried cohabiting fathers as well as multipartnered fertility (having children with multiple partners) altered men’s impact on children’s outcomes?

**Recent Research Results**

The impacts of fathers on children can begin before birth (see\(^1\)). Fathers may have heritable physiological impacts on their children via genetic and epigenetic mechanisms that begin to emerge shortly after conception\(^2\) and which may influence maternal investment during pregnancy.\(^3\) Older fathers tend to transmit more mutations to their offspring,\(^4\) while early childhood paternal stressors predict children’s adolescent gene methylation patterns (a type of chemical modification of DNA).\(^5\)

The presence of fathers has mixed effects on their children’s survival.\(^6\) Oral histories from small-scale societies suggest that fathers help protect their children against enemy threats,\(^7\) while in the U.S., having no father listed on the birth certificate increases the odds of infant mortality.\(^8\) A primary risk factor for child abuse or infanticide in contemporary countries as well as smaller-scale societies is the presence of an unrelated male stepfigure, such as a boyfriend, reminding us that father figures’ impacts on children can be deleterious too.\(^9,10\)

An evolutionary perspective suggests that father involvement has been important in the increased fertility of human hunter-gatherers compared with the other great apes.\(^11,12\) That observation contrasts, however, with a world today where fertility levels are plummeting in most countries, with fathers typically investing large amounts of resources and care in few offspring over prolonged periods.\(^13,14\) In this latter case, the time and resources provided by fathers may help develop a child’s social and educational capital, in turn helping him/her succeed socially as an adult.\(^15\)
Fathers have an array of impacts on children’s socioemotional outcomes. Studies testing for these potential types of influences have considered both dichotomized father absence/presence and more continuous assessments of paternal care. Cautions in drawing conclusions in this literature include the challenges to isolate specific paternal influences on specific childhood outcomes, given the multitude of potential covarying factors.

A variety of studies suggest that fathers’ engagement positively impacts their children’s social competence, children’s later IQ and other learning outcomes. The effects of fathers on children can include later-life educational, social and family outcomes. Children may develop working models of appropriate paternal behaviour based on early childhood cues such as father presence, in turn shaping their own later partnering and parenting dynamics, such as more risky adolescent sexual behaviour and earlier marriage. Paternal engagement decreases boys’ negative social behaviour (e.g., delinquency) and girls’ psychological problems in early adulthood. Fathers’ financial support, apart from engagement, can also influence children’s cognitive development.

While father absence has been associated with a host of negative children’s outcomes, including increased risk of dropping out of school and lower educational attainment, poorer physical and mental health, and behavioural problems, higher levels of involvement by nonresident fathers may assuage the negative effects of father absence on children’s outcomes. Quality of the parents’ relationship before divorce, or of the pre-divorce father/child relationship, can also be an important factor: children fare worse following divorce when pre-divorce relationships were good and fare better when pre-divorce relationships were poor, suggesting children are sometimes better off without a father if the father’s relationship to the child or the mother was not good. The growing trend in multipartnered fertility, along with high rates of nonmarital births, means that many men are fathering children from multiple women at a distance, a trait that is associated with greater externalizing behaviours and poorer health among children.

Effects of children on fathers vary with respect to attributes of fathers and of children. Boys whose fathers engaged in physical play but without excessive direction were rated as more popular by their teachers. Effects of fathers may vary across children’s ages, with fathers of adolescent sons frequently playing important roles in those son’s transitions, as seen among Arnhem land Australian aborigines. Among the Aka hunter-gatherers of Central African Republic, males of varying ages report that they predominantly learned subsistence and social behavioural norms from their fathers.
Stepfathers are widespread not only in modern industrial societies but also in subsistence-level societies as well.\textsuperscript{6,51,52} Many studies have found that, compared with resident biological fathers, stepfathers invest less in the children who live with them, both in the United States\textsuperscript{37,39,53} and other cultures.\textsuperscript{54-56} Stepchildren are more likely to have emotional and behavioural problems than resident genetic offspring,\textsuperscript{39,40} although there is evidence that children who have close relationships with their stepfathers have better outcomes.\textsuperscript{41,57}

Gay fathers tend to be economically well-off, one means by which their children may garner social advantages relative to other children, while additional research has shown that children of gay fathers did not report differences in sex-typed behaviour compared with parents of other family configurations.\textsuperscript{58} A large literature shows that parents tend to transmit values to their children along socioeconomic status lines, with middle class parents typically imparting different values from parents in lower socioeconomic strata.\textsuperscript{59,60} However, little of this work has examined fathers in particular, as distinct from mothers.

**Research Gaps**

Global interconnectedness, including in the patient pool faced by clinicians and constituents served by policymakers, also means that more research on the cultural scope of fathering and its impact on children is warranted. For example, how do immigrant children fare when faced with a new social context to which their fathers’ cultural values and behaviours must be adapted? How do cohabiting fathers differ from married fathers, and does their respective involvement with children impact children differentially? How does the growing trend in multipartnered fertility impact children? Much of our understanding on fathers and children’s outcomes stems from cross-sectional or retrospective studies; we need more large, prospective studies, especially internationally, with greater ability to address causal inference. Lastly, as some men are pursuing fatherhood at later ages than ever, men with multiple partners may have children the same age as their grandchildren. What are the effects of aging fathers on children’s outcomes?

**Conclusions**

Despite the increase in nonmarital childbearing and subsequent increase in nonresidential fathers, men continue to play important roles in their children’s lives. Fathers can influence their children by providing direct care, as well as indirectly through financial support and social modelling. Father involvement has impacts which begin prenatally and extend through the
child’s life course. Men’s investment in offspring can influence offspring survival, health, socioemotional outcomes, social competence, and educational attainment. Much of the research examining the impacts of fathers on children has compared father-absent versus father-present households, rather than degrees of father involvement. The literature shows that father absence tends to correlate with poorer children’s outcomes, including lower education attainment, poorer health, greater emotional and behavioral problems, with effects lasting well into adulthood (as measured by socioeconomic status and marital patterns). However, it is unclear to what extent self-selection has biased these studies, as men who remove themselves from a child’s residence may differ in many unobserved ways from men who choose to remain.

Implications for Parents, Services and Policy

Human families, including roles of fathers, can be quite flexible: we should neither be too fixated on the effects of one caregiver (fathers) nor dismissive of the effects of these same fathers. We should situate fathers’ effects in social and individual context, whereby (say) effects may be more pronounced and important in isolated nuclear families in low-fertility high social capital contexts, but less visible in extended families with higher fertility and more substitutable forms of childcare. Many features of male involvement are structured by the relationship with a child’s mother, which can also inform fatherhood intervention policy. Child characteristics (age, sex, disability, personality) vary and are part of variable father-child relations. Direct care can matter, but so does indirect care (such as ‘breadwinning’), and both should be considered in assessing effects of fathers on children. The effects of fathers on children encompass a diversity of outcomes (e.g., socioemotional, behavioural risk-taking).
