Introduction

Maternal and paternal depression are prevalent among 20% of women\textsuperscript{1-4} and 10% of men\textsuperscript{5,6} during the perinatal period. Mental health problems (of which depression is the most common) are even more prevalent in nearly half of low-income families, given the elevated risk due to factors such as traumatic life events, low social support, adolescent or single parenthood, systemic racism, and health, economic, and education inequities.\textsuperscript{4,7-9} Children of parents with depression may experience a range of negative outcomes including developmental delays, cognitive impairments, and attachment insecurity, along with increased risk for developing mental health issues.\textsuperscript{10,11} Given the vast and growing number of perinatal families they serve, home visiting programs are in a unique position to address parental depression and substance abuse as well as issues that impact mental health and family well-being, including intimate partner violence. In this chapter, we focus on research related to home visiting programs’ identification and responses to impact parent mental health, identify gaps in existing research, and provide recommendations for research, practice and policy communities to effectively address parental depression, substance abuse, and experiences of intimate partner violence, through home visiting.
Home visiting focuses on fostering healthy child development by supporting positive parenting practices, including supports for parents’ socioemotional and socioeconomic well-being, through direct services and referrals to other professional services in their communities. Home visiting programs are implemented in large scale across 46 countries and in limited scope among 55 countries, reflecting increasing global efforts to optimize child development, maternal health, and family well-being over the life course. Research has demonstrated that up to 50% of parents served by home visiting have experienced clinically elevated levels of depression during the critical first years of their child’s development. In a recent U.S. population survey, 1 in 4 women and 1 in 10 men identified having experienced intimate partner violence, with nearly 1 in 10 identifying reproductive coercion. In a national telephone survey, 1 in 5 children ages 17 and under had witnessed family violence in their lifetime, with one-third of those children ages 0 to 5. In a recent National Survey on Drug Use and Health, 1 in 10 pregnant women surveyed reported drinking alcohol, and among that subset, 40% reported using one or more other substances in addition to alcohol. Furthermore, the impact of depression, substance abuse, and intimate partner violence can have multigenerational impacts on developmental, social, education, economic, health and mental health outcomes. Identifying parents with, or at risk for, depression and substance abuse, and those experiencing intimate partner violence, can improve family outcomes and foster healthy child development, improving multi-generation outcomes.

Depression in new parents has profound and often long-term negative effects on parenting and child development. Depression can impair positive parenting practices, such as difficulty reading infant cues, struggles to meet the social and emotional needs of their children, and less tolerance of child misbehaviour. Children of parents with depression, particularly if they are exposed in their first year, are more likely to be poorly attached to their caregivers, experience emotional and behavioural dysregulation, have difficulty with attention and memory, and are at greater risk for psychiatric disorders in childhood and adulthood. Symptoms of depression and substance abuse, and experiences of intimate partner violence, can negatively impact engagement with home visits and connecting with referrals for parent and child services to address health, development, education and economic stability. Furthermore, even when they are successfully identified and referred to mental health providers, few parents receive effective treatment. A majority of surveyed home visitors perceived barriers and limited access for families to receive needed
services, with only 1 in 5 parents connecting with designated mental health, substance abuse, and intimate partner violence referrals for needed services.

**Research Context**

Recommendations for systematic depression screening and preventive interventions for perinatal women at risk for depression, have guided standards of care across healthcare and human service systems, providing increased opportunities for identification and service coordination to provide appropriate, successful referrals and services. Furthermore, federally funded home visiting programs are required to meet performance measures to assess all clients for depression, to provide referrals to services for parents who screen positive for depression, as well as screening for experiences of intimate partner violence and providing referrals and IPV resources as needed.

With home visiting’s increased responsibility to effectively identify, refer, and provide enhanced services for families with mental health issues and family violence, systematic evaluation and improvement of coordinated services to optimize referrals are critical. Systemic supports for mental health consultation and mental health-related training for home visiting programs and staff improve knowledge, effectiveness, well-being and retention, all of which promote sustainability and community impact. Quality improvement collaborations have provided a clearer understanding of the necessary supports, policies, procedures, and training to maximize the impact of home visiting on parent and child mental health, along with the opportunity to promote strategy implementation, adaptation, and sustainment of effective home visiting practices.

Longitudinal studies have shown the efficacy of home visiting on maternal and child health outcomes, with maternal depression and other mental health issues remaining one of the most challenging areas of impact. Even with commendably high rates of depression screening in home visiting, significant challenges remain to successfully connect those in need with effective mental health services. In recognition of the prevalence of mental health challenges parents in home visiting experience, interventions aimed at preventing and treating maternal depression have been developed and tested within home visiting settings, along with interventions to address substance misuse, and to address intimate partner violence experiences and parent and child safety. Alongside intervention development, models of trauma-informed approaches to assess adverse childhood experiences (ACEs) and traumatic events have been developed and tested,
within the context of targeted, universal approaches to brief home visiting services.\textsuperscript{39,40}

**Key Research Questions**

There are three key research questions:

- What is the best approach to preventing and treating depression in new parents participating in home visiting programs?
- How can home visiting have the greatest impact through systematic screening and service coordination for families experiencing mental illness, substance abuse, and intimate partner violence?
- What are the most effective approaches for home visiting programs to effectively screen, refer, and provide effective interventions for parents with mental health issues?

**Recent Research Results**

*Home visiting and parental mental health*

Over the past decade, as home visiting has been increasingly implemented, funded and evaluated, researchers have studied the impact of home visiting programs’ screening, referral, and intervention efforts on maternal depression and other significant mental health risks and challenges, including substance abuse and intimate partner violence.\textsuperscript{23-26} Results from the Mother and Infant Home Visiting Program Evaluation, which evaluated 88 home visiting programs from 12 states, showed that over 75\% of home visitors rated their self-efficacy and levels of implementation support for parenting and child development outcomes highly, while less than 60\% endorsed adequate implementation support to address mental health issues.\textsuperscript{25} Correspondingly, home visitors who had received training to assess mental health with families were more likely to discuss these issues within home visiting practice than those who had not received specialized mental health training.\textsuperscript{25}

There is evidence that parental depression can have a negative impact on the effects of home visiting programs.\textsuperscript{50} Depression has been associated with negative views of parenting and limited knowledge of child development.\textsuperscript{51} In the Early Head Start Research and Evaluation Project, compared with non-depressed mothers, mothers with depression showed deficits in mother-child interaction and in obtaining education and job-related goals.\textsuperscript{23} However, mothers with depression also showed gains in some aspects of engaging with their children during structured tasks.
Duggan et al.\textsuperscript{52} found that mothers with depression and lower levels of attachment anxiety showed improved sensitivity to child cues relative to those with higher levels of attachment anxiety and those who did not receive home visiting. The Nurse-Family Partnership model research has consistently found that mothers with low psychological resources, a construct that includes some symptoms of depression, benefit most from home visiting.\textsuperscript{57} Taken together, it is evident that depression affects home visiting and family outcomes in complex ways.

\textit{Identification and response to parent mental health challenges}

The U.S. federal Maternal, Infant and Early Childhood Home Visiting program has developed performance indicators and outcome measures for funded home visiting programs to screen home visiting clients for depression within three months of enrollment or birth, and to screen for intimate partner violence within six months of enrollment, using validated tools.\textsuperscript{10} Furthermore, caregivers who screen positive for depression should receive a referral for mental health services, which can include mental health interventions within the home visiting program as well as external service referrals. Parents who screen positive for intimate partner violence should receive referral information for IPV resources and services. Although not a requirement, the majority of home visiting programs surveyed also screen for substance and tobacco use, and provide referrals for appropriate services and interventions,\textsuperscript{26} with research guiding practice in effective service coordination, including engaging with community partners in other health and human services settings.\textsuperscript{53,54} These revised standards of home visiting care in the U.S. have driven nationally scaled implementation evaluation and collaborative quality improvement efforts to support the goals of improving parent and child mental health to advance multi-generational family and community health, educational, and economic outcomes.\textsuperscript{24,25}

\textit{Service coordination}

Effective service coordination is crucial in home visiting to meet both child and parent needs, and is driven by four key components—screening, referral, linkage, and follow-up—necessitating participation by home visitors, caregivers, and service organizations, to ensure successful receipt of services for families dealing with depression, substance abuse, and intimate partner violence.\textsuperscript{24,26} Home visiting researchers have developed service coordination models and guidance for building strong partnerships between home visiting, health care, and other community-based agencies to facilitate successful referral connections and receipt of effective interventions.\textsuperscript{53,54} Recommendations to address family mental health needs through home visiting service
coordination include: (1) assessing current screening, referral and coordination processes, using an evidence-based approach (e.g. the Home Visiting Applied Research Collaborative Coordination Toolkit\(^5\)); (2) professional development and supports for home visitors to conduct mental health-focused services with families, including training, reflective supervision, and mental health consultation; (3) participation in a collaborative home visiting quality improvement and innovation network;\(^2\) and (4) partnering with researchers to identify, develop, and evaluate strategies to address needs specific to the families and communities served.\(^5\) To effectively complete screening, referral, and linkage with services for home visiting families with mental health needs, health systems and community agencies should also assess service coordination, capacity, and opportunities to improve access and outreach.\(^2\)\(^,\)^\(^2\)\(^5\)

*Mental Health Consultation*

To support the expanding roles and responsibilities of home visiting programs to identify and support families experiencing depression, substance abuse, and intimate partner violence, home visiting programs are integrating Mental Health Consultation into program operations and teams. Mental health consultant supports include staff training on mental health topics, reflective group and individual supervision, and accompaniment on home visits for individual families with identified mental health needs.\(^3\)\(^2\)\(^,\)^\(^5\)\(^7\)\(^\)\(^9\) The federally-funded Project Launch program promotes preventive behavioral health through integration with primary care to better meet the needs of children and their families.\(^3\)\(^2\)\(^,\)^\(^6\)\(^0\) Many home visiting grantees have incorporated Infant Mental Health Consultants to support home visitor learning and efficacy in assessing and addressing mental health with parents and children. The vast majority (90%) of home visitors from programs with mental health consultation reported increased professional growth, knowledge about children’s mental health, identification of appropriate follow-up services to meet specific parent and child mental health needs, and reduced compassion fatigue. Further innovation and evaluation in promoting partnerships between home visiting, pediatric, and community services is needed to achieve optimal outcomes for parent and child mental health.\(^3\)\(^2\)

*Quality improvement*

Quality improvement collaborations among home visiting programs provide the opportunity to maximize the effective application and impact of mental health screening, referral, service provision, and follow-up for caregivers in need of interventions and resources to address their mental health needs. In a recent cohort of 14 home visiting programs from 8 states, the home
visiting collaborative improvement and innovation network (HV-CoIIN)\textsuperscript{61} created a community of practice, support, and evaluation, to increase depression screening and connection with evidence-based services for those who screen positive for depression risk. In its first cohort, results showed increased rates of depression screening (from 84\% to 96\%), increased receipt of evidence-based mental health services (from 42\% to 66\%) and improvements in depression symptoms (from 51\% to 60\%) among women who accessed mental health services, including referrals to behavioral healthcare providers as well as home visitor provision of mental health interventions.\textsuperscript{24} In the current, HV-CoIIN cohort, intimate partner violence has been added to the focal topics for innovation and quality improvement, with 21 states, 136 home visiting programs, and one tribal nation participating, cumulatively, since 2013.\textsuperscript{61}

\textit{Treatment and prevention of depression in home visiting}

Because pregnant and new parents with depression rarely obtain effective treatment in the community, several approaches have been developed that provide treatment in the home. Ammerman and colleagues created In-Home Cognitive Behavioral Therapy (IH-CBT).\textsuperscript{62} IH-CBT is a structured and manual-driven approach that is provided by a master’s degree-level therapist. It is an adapted form of an evidence-based treatment for depression that has been modified for the home setting, addresses the unique needs of new mothers who are socially isolated and live in poverty, and engages the home visitor to facilitate a strong collaborative relationship in order to maximize outcomes for mothers and children. A recent clinical trial\textsuperscript{63} found that mothers with major depressive disorder receiving IH-CBT alongside home visiting, relative to those receiving home visiting alone, had lower levels of diagnosed major depressive disorder at post-treatment (29.3\% vs. 69.0\%) and at three-month follow-up (21.0\% vs. 52.6\%). They also reported larger drops in self-reported depressive symptoms, increased social support, lower levels of other psychiatric symptoms and increased functional capacity. This intervention has been found to be cost-effective\textsuperscript{64} and is now being disseminated as “Moving Beyond Depression.”\textsuperscript{65}

Beeber et al.\textsuperscript{66} conducted a clinical trial of interpersonal psychotherapy (IPT) with 80 newly immigrated Latina mothers ages 15 years or older who were participating in Early Head Start. Participants with depression were randomly assigned to IPT treatment or a “usual care” condition. Treatment was delivered by psychiatric nurses who partnered with a Spanish interpreter. Eleven sessions were provided by the team, and five additional boosters were administered by the interpreter. Results showed significant drops in self-reported depression in the IPT relative to the usual care group that were maintained at one-month post-treatment. Furthermore, IPT delivered
to parents of Early Head Start-enrolled infants and young children showed a significant impact on positive parenting practices among low-income mothers experiencing depression symptoms, compared with mothers who did not receive IPT from a nurse home visitor.\textsuperscript{67}

Segre, Brock and O’Hara\textsuperscript{68} implemented six Listening Visits, either during home visits or during prenatal healthcare office visits, delivered by home visitors or obstetric clinic staff. Listening Visits focused on empathic listening, collaborative problem solving, and assessment of need for additional mental health treatment. Results indicated that women receiving the Listening Visit intervention experienced significantly reduced depression symptom severity and improved quality of life compared to women receiving standard home visiting or prenatal services, including a clinically significant reduction in depression symptoms.\textsuperscript{68} Delivery of Listening Visits by non-mental health professionals at the point of care, in the participant’s primary language (in this case English or Spanish), can navigate the barrier of stigma related to engaging in mental health services.

Tandon and colleagues have adapted the Mothers and Babies (MB) intervention\textsuperscript{69} for use in home visiting as a depression prevention intervention. MB is a cognitive-behavioural, attachment-based intervention that can be implemented as a group or individual modality. Findings from the first RCT of Mothers and Babies groups in home visiting\textsuperscript{70,71} showed depressive symptoms declined at a greater rate for intervention participants than usual care participants, with the strongest effects found at six months post-intervention, including less likelihood than usual care participants to develop a depressive episode (14.6\% vs. 32.4\%). Another study of MB groups in home visiting showed improvements in depression, stress, and coping, but the long-term effects waned at the 6-month post-intervention time point, indicating the need for supports to sustain positive gains.\textsuperscript{72} In both of these studies, the group facilitator was a master’s-level clinician. In comparison, a recent cluster RCT of MB groups in home visiting, delivered by mental health clinicians compared with paraprofessional home visitors, found that home visitor facilitators were equally effective in achieving depression symptom reduction among prenatal group participants as their mental health clinician counterparts, further supporting the efficacy of the intervention when delivered by home visitors.\textsuperscript{73}

Given the predominance of individual home visits as the primary modality, MB has been adapted into a series of brief individual sessions for delivery alongside a usual home visit by home visitors,\textsuperscript{74} and has shown to have a significant effect in reducing depression and anxiety symptoms at an increasing rate over time at 3 and 6 months postpartum compared with usual home visiting services.\textsuperscript{75} Scaling is in progress across U.S. home visiting programs. A Fathers and Babies (FAB)
intervention has been developed and pilot tested, and is ready to scale to expanded implementation and effectiveness trials.\textsuperscript{76,77}

\textit{Interventions to address intimate partner violence in home visiting}

In a systematic review of home visiting effectiveness in reducing partner violence (IPV), six home visiting studies met inclusion criteria of measuring IPV as an outcome while testing interventions for women and children exposed to IPV.\textsuperscript{78} Three studies showed statistically significant reductions of IPV, wherein their protocols directly addressed the partner violence and supported the abused partner.\textsuperscript{19,79-81} Successful approaches included providing safety strategies, parenting support, and referral to community services, with a dual focus on preventing child abuse and further abuse to the abused parent.\textsuperscript{78}

\textit{Interventions to address substance abuse in home visiting}

A systematic review of 12 qualitative and three mixed methods studies assessing family-focused practices with families experiencing parent mental illness and substance abuse, emphasizes the importance of assessing need and offering services for the family as a whole, indicating that in both research and practice there are limited examples with both parents, or the whole family unit, whose perspectives and participation are included.\textsuperscript{20} The TIES model (Team for Infants Exposed to Substance abuse) provides a trauma-informed approach to supporting families dealing with substance abuse, to improve child and parent outcomes, and interrupt intergenerational transmission of trauma, substance abuse, toxic stress, and other health disparities.\textsuperscript{43} This two-role model pairs a master’s-level social worker with the parent, in a therapeutic alliance, and an expert parenting specialist to support the mother-child relationship and promote bonding and positive parenting practices, using a strengths-based framework. In addition, the home visiting team works with participants to develop goals and support with socioeconomic stability for the family.

\textbf{Research Gaps}

Further examination of how evidence-based practices are adapted and sustained in home visiting should identify key factors that inform best practices in scaling and sustaining effective interventions to support parent and child mental health. More research is needed on home visiting approaches and interventions that engage the family system, including both parents and other significant caregivers, to maximize positive multigenerational outcomes. Coordinated community-level strategies and partnerships across family-serving systems are needed to have the greatest
population health impact, especially among families and communities with the greatest health inequities. Finally, there is a need to better understand the long-term impacts of home visiting on parental and child mental health, and the potential for long-term quality improvement collaborations between home visiting systems and community partners to support parent and child mental health.

Conclusions

The scope of work and responsibility of home visiting programs and home visitors has grown significantly over the last decade. Staff need mental health training and supports for a service system that is often under-resourced. They also need up-to-date training on advances in evidence-based screening, service coordination, and interventions to support parent and child mental health within a flexible delivery system. Opportunities for population health and health equity impacts are within reach, with strong evidence supporting the impact of universal home visiting with targeted assessment, referral, and interventions to address mental health challenges. By expanding the scope of home visiting services to the whole family, home visiting can have greater impact on family mental health and well-being, as well as socioeconomic stability and health equity.

Implications for Parents, Services and Policy

Systematic screening for depression, substance abuse, intimate partner violence, and trauma history should take place in health and human service settings where pregnant women and parents with infants and young children interact. However, there are challenges to achieving this systemic change in screening procedures, along with challenges to making effective linkages to appropriate resources, once client needs are identified. Strengthening community partnerships across systems can provide a pathway and capacity for improved service coordination and outcomes for families. To support improved service coordination within home visiting, the Home Visiting Applied Research Collaborative (HARC) provides a service coordination toolkit, guided by the following principles: that service coordination collaborations be family centered, equitable, adaptable, interdisciplinary, and focused on population health. Home visiting programs need to provide training and support for home visitors to effectively address mental health during home visits. Training should provide guidance on balancing conversations about family-identified needs with discussions about mental health and other psychosocial risk factors that can impair effective parenting, child development, and family well-being. The use of reflective supervision, coaching,
and infant mental health consultation are approaches that can be used effectively to develop and maintain staff skills, while helping to better meet the mental health needs of families. Research efforts to augment home visiting services with mental health interventions aimed at preventing depression, substance abuse, and intimate partner violence, need to examine mechanisms that impact intervention effectiveness and contextual factors that impact implementation and sustainability, as mental health interventions within home visiting are scaled.
